AN ECONOMIC INDEX FOR DETERMINING THE RELATIVE VALUE OF MILK AND FAT IN PREDICTED DIFFERENCES OF BULLS AND COW INDEX VALUES OF COWS

by H. D. Norman and F. N. Dickinson

The comparison of bulls and cows, based on the profitmaking potential of their daughters, is receiving more attention by dairymen as they become increasingly more aware of the greater profitability associated with superior genotypes. Heretofore, the transmitting abilities of bulls and cows have been evaluated separately on the basis of the economically important traits of milk and fat yield. However, the economic value of the produce depends both on the quantity of milk and its milk fat content. In a few parts of the country, other milk components, primarily protein or solidsnot-fat, are also included in the milk-pricing scheme, but this practice is not widespread and information on genetic merit for these components is almost entirely lacking. Therefore, the discussion in this letter relates the transmitting ability of bulls and cows for milk and fat to the economic value of milk which their daughters would be expected to produce.

Relative Economic Importance of Predicted Differences for Milk and Fat in Sire Summaries

The measures of transmitting ability most commonly available on a bull in the United States are the Predicted Differences (PD) for milk and for fat. The PD is the expected deviation of the bull's progeny from their herdmates in breed average herds; in other words, it is one-half the bull's breeding value. Having more than one rating of production for each bull (PD milk and PD fat) has frequently posed problems for breeders and sire committees in determining which available bulls should be selected for service. For instance, it would not be unusual to want to choose for breeding purposes between Bull A having PD's of +1,000 lb. for milk and +10 lb. for fat and Bull B having PD's of +500 lb. for milk and +30 lb. for fat. Regardless of the extent of evaluation in other traits, it seems desirable to know the difference in expected total income from milk produced by daughters of these two bulls.

Milk price depends upon the milk fat percentage in almost all areas of the United States. A consequence is that in some States sire lists are ranked according to PD for milk while others are ranked by PD for fat. Spahr 1/ and Wilton and Van Vleck 2/ have given procedures to evaluate the relative emphasis that should be given to milk versus fat, and have given examples of their indexes using specific prices. Spahr's study showed that gross income within the five breeds was more highly correlated with fat than milk yield. Wilton and Van Vleck showed that under a typical New York pricing system (\$5.00/cwt. for 3.5% milk with a differential of \$0.06/0.1%/cwt.), selection based either on PD milk or PD fat, would be, respectively, only 95 or 92 percent as effective in increasing value of product as would selection considering both traits. Since gains are cumulative each generation, such differences become extremely important for increasing herd

<sup>1/</sup> Spahr, S. L. Relative economic importance of milk and milk fat percentage in selecting artificially inseminated proven dairy sires. J. Dairy Sci., 50:847. 1967.

<sup>2/</sup> Wilton, J. W., and Van Vleck, L. D. Sire evaluation for economic merit. J. Dairy Sci., 52:235. 1969.

profitability over a long period of time. This means that selecting for both milk and fat is necessary for maximum economic progress, even though progress in each trait will be slower.

Gross income can be determined using fat yield instead of fat percent if milk yield is given. In fact, comparing dollar income using PD milk and PD fat has one advantage over using PD milk and fat percent. The advantage is that the economic value resulting from the Predicted Differences of milk and fat are additive, and are therefore independent of the herd or breed averages. This is not so if the indexes are based on PD milk and fat percent. This assures, with some certainty for the immediate future, that decisions in selecting sires based on both PD milk and PD fat can be made while ignoring the emphasis that dairymen gave to these traits in their herds in the past.

An economic index predicting gross income from milk and fat production can be used to simplify selection among bulls of the same breed. The availability of an index for net income, one that would consider such factors as feed intake, efficiency, health costs, calving interval, and herd life, would be even more useful, but certainly more difficult to obtain for individual bulls. Miller, Hooven, and Smith 3/ have results to indicate that as the value of milk produced increases 1 dollar, income over feed cost increases about 80 cents. Therefore, it appears that the relationship between gross income and net income is quite high, and an economic index which predicts gross income would be effective for increasing net income as well.

The formula for computing gross income based on Predicted Differences, breed averages, and prices for milk and milk fat is shown in Appendix I. This formula can be used to calculate the gross income per lactation for the daughters of a bull.

<sup>3/</sup> Miller, R. H., Hooven, N. W., and Smith, J. W. Associations among measures of economic efficiency. J. Dairy Sci. (Submitted for publication)

A second formula for comparing the daughters of different bulls of the same breed is shown in Appendix II. This formula expresses the expected income for the daughters of a bull based on PD's for milk and fat relative to the breed average, for a specific pricing system. This permits the direct comparisons of individual bulls to breed average in the same manner as does PD's, but on the relative gross income expected from their daughters.

The formula in Appendix II was solved using various combinations of milk price and fat differential. These results are shown in tables and give the deviation from breed average income per lactation that can be expected from the daughters of bulls at various levels of PD's for milk and fat. Forty-five tables are presented, based on 3.5 percent milk prices ranging from \$4.50 to \$8.50 per cwt. by increments of \$0.50, and fat differentials of \$0.07 to \$0.09 at increments of \$0.005. These tables provide a quick measure of relative gross income and should be applicable to most present pricing systems as well as those in the immediate future. A list of table numbers according to the various milk prices and test differentials is given in table 1.

TABLE 1.--List of tables by milk and milk fat prices

| Price of milk per cwt. at | Milk fat d | lifferentia<br>in ce |         | 1 percen          | t/cwt. |
|---------------------------|------------|----------------------|---------|-------------------|--------|
| 3.5 percent test          | 7          | 7½                   | 8       | 8½                | 9      |
| (\$)                      |            | Table r              | numbers |                   |        |
| 4.50                      | 2          | 3                    | 4       | 5                 | 6      |
| 5.00                      | 7          | 8                    | 9       | 10                | 11     |
| 5.50                      | 12         | 13                   | 14      | 15 <sup>4</sup> / | 16     |
| 6.00                      | 17         | 18                   | 19      | 20                | 21     |
| 6.50                      | 22         | 23                   | 24      | 25                | 26     |
| 7.00                      | 27         | 28                   | 29      | 30                | 31     |
| 7.50                      | 32         | 33                   | 34      | 35                | 36     |
| 8.00                      | 37         | 38                   | 39      | 40                | 41     |
| 8.50                      | 42         | 43                   | 44      | 45                | 46     |

4/ Approximately the average U.S. price for 1970, Dairy Situation, Economic Research Service. USDA DS-333. November 1970.

The income values in tables 2 through 46 are based on Mature Equivalent production. Actual deviation in daughters' first-lactation income from herdmates would be slightly less than that shown in the tables. This, of course, would depend upon the age of the daughters. Generally, differences in first-lactation yield would be about 80 to 85 percent of those at maturity, so dollar value of production would be the same percentages of these table values.

It is suggested that when using these tables the milk price should be the gross price per hundredweight minus handling charges and any other deductions which are taken out before the dairyman receives his milk check. This should result in relative deviations in gross income that are closer to the effective income which the dairyman receives. Milk prices vary considerably throughout the year, so the prices used should be those expected from the total volume of milk to be sold.

For illustrating the use of the tables, compare Bulls A and B referred to previously using two different pricing systems.

Example 1: (from table 15)

# Average 1970 U.S. pricing system:

Milk price is \$5.00/cwt. for 3.5% test Milk fat differential is \$0.085/0.1%/cwt.

These comparisons are shown below:

|        | PD milk    | PD fat  | Value of production |
|--------|------------|---------|---------------------|
| Bull A | +1,000 lb. | +10 lb. | \$33.75             |
| Bull B | +500 lb.   | +30 lb. | \$38.12             |

The milk produced by Bull A's daughters will be worth \$33.75 more than their breed average herdmates, whereas the milk produced by Bull B's daughters will be worth \$38.12 more than their herdmates. Thus, when average U.S. milk prices are used, Bull B is economically superior to Bull A. Yet, if ranked on PD milk, Bull A would be 500 pounds above Bull B and might well be in higher demand because of this. Bull A would deserve this higher demand because of expected income under a system in which dairymen are producing milk for fluid utilization according to Class I prices.

For these conditions a high fat test is not as important, and so more emphasis should be given to PD milk.

Example 2: (from table 30)

# Typical 1970 Class I pricing system:

Milk price is \$7.00/cwt. for 3.5% test Milk fat differential is \$0.085/0.1%/cwt.

Bull A's daughters are expected to gross \$48.75 more than breed average herdmates, whereas Bull B's daughters are expected to gross \$45.62 above such herdmates. Under these conditions, Bull A has a slight advantage in increasing total income from milk yield.

Apparently Spahr's  $\frac{5}{}$  and Wilton and Van Vleck's  $\frac{6}{}$ different conclusions about the relative importance of milk and fat yields resulted partially from the use of different price ratios of base milk to fat differential. It appears that at the average U.S. prices for 1970 (\$5.50 and \$0.085, for milk price and fat differential), a change of a standard deviation in PD fat is as important as a change of a standard deviation in PD milk within the Holstein breed. Under some pricing systems (those having a high ratio of milk price to test differential), the bulls with the highest PD milk will return the highest income from milk production; in other systems (those with a low milk to test ratio), the highest profit makers are the highest PD fat bulls. Within the higher fat percentage breeds it would be easier to increase economic merit selecting for fat yield than for milk yield. Within all breeds, bulls can be expected to shift ranks somewhat under different pricing systems.

In some areas, payment is being made for total yield of various constituents other than fat, especially solidsnot-fat or protein. Pricing schemes of this type are a refinement of past pricing systems. The production of milk solids-not-fat and protein will be emphasized in the future more than has been in the past, and payment will probably be made directly on the level of these milk components. fore, dairymen should give some consideration to the possible change in the pricing of these milk components in the future when selecting bulls. Unfortunately, at the present time little is known about the levels of protein and solids-notfat which bulls transmit to their daughters, except what can be inferred from the average genetic relationships of the levels of these components to milk yield and fat content.

<sup>5/</sup> See footnote 1.6/ See footnote 2.

# Relative Economic Importance of Cow Index Values for Milk and Fat

The formulas in Appendix I and II and the values in tables 2 through 46 can be used to estimate the expected gross income of daughters of cows, the same as for the daughters of bulls. The terms TA<sub>m</sub> and TA<sub>f</sub> used in the appendix formulas represent the genetic transmitting ability of the parent (sire or dam) for milk or fat. Therefore, if a bull's daughters are to be evaluated, the bull's PD's for milk and fat are used. Similarly, if a cow's daughters are to be evaluated, the cow's Cow Index Values for milk and fat are

daughters are to be evaluated, the bull's PD's for milk and fat are used. Similarly, if a cow's daughters are to be evaluated, the cow's Cow Index Values for milk and fat are used in the formulas. Since PD's and Cow Indexes are both estimates of genetic transmitting ability, they can be used for the same purpose in looking up values in the tables.

# Summary

The income that dairymen receive for milk in most areas of the United States depends both on total quantity and milk fat content. Thus, for maximum economic progress bulls and cows should be selected for both milk and fat even though progress in each will be slower. At present average U.S. prices, a standard deviation increase in fat is as beneficial as a standard deviation increase in milk in increasing economic value. With variation in pricing systems, it appears that in some areas it would be to the breeders' advantage to give more emphasis to milk than fat, while in other areas it seems the reverse should be true. Tables are provided so that bulls and cows can be evaluated on economic merit using the appropriate milk price and fat differential.

The formula for computing expected gross income for milk produced by the daughters of a specific bull or cow is:

# Equation 1

$$I = (BA_m + TA_m) \times (P - D \times T_b) + (BA_f + TA_f) \times (D \times 100\%)$$

## where:

- I is the expected total income for milk produced in a 305-day lactation.
- $^{\mathrm{BA}}_{\mathrm{m}}$  and  $^{\mathrm{BA}}_{\mathrm{f}}$  are the breed averages in units for milk and fat yield, respectively. (See USDA-DHIA Sire Summary)
- ${
  m TA}_{
  m m}$  and  ${
  m TA}_{
  m f}$  are the genetic transmitting abilities in units for milk and fat, respectively. If the daughters of a bull are being evaluated, PD for milk is used for  ${
  m TA}_{
  m m}$ , and PD for fat is used for  ${
  m TA}_{
  m f}$ . If the daughters of a cow are being evaluated, the Cow Index Value for milk is used for  ${
  m TA}_{
  m m}$ , and the Cow Index Value for fat is used for  ${
  m TA}_{
  m f}$ .
- P is the price paid for a unit of milk at the base test.
- D is the test differential or the change in value of a unit of milk for each change of 1 percent in fat test.

 $T_{b}$  is the base test in percent.

# Example 3:

The expected gross income for milk produced by daughters of Bull C with a PD for milk of +1,200 lb. and a PD for fat of +40 lb. is to be calculated using the following information:

 $BA_{m} = 14,250 \text{ lb.}; BA_{f} = 525 \text{ lb.}; P = $0.055/1b.$ (obtained from \$5.50/cwt.).

$$D = \$0.0085/\%/1b$$
. (obtained from  $\$0.085/0.1\%/cwt$ .).

$$T_b = 3.5\%$$

Since the bull's PD for milk and fat are used for  $TA_{m}$  and  $TA_{f}$ , then  $TA_{m} = 1,200$  lb. and  $TA_{f} = 40$  lb.

The index formula from equation 1 is solved as follows:

$$I = (BA_m + TA_m) \times (P - D \times T_b) + (BA_f + TA_f) \times (D \times 100\%)$$

$$I = (14,250 \text{ lb.} + 1,200 \text{ lb.}) \times (\$0.055/\text{lb.} - (\$0.0085/\%/\text{lb.}) \times (3.5\%)) + (525 \text{ lb.} + 40 \text{ lb.}) \times (\$0.0085/\%/\text{lb.}) \times 100\%)$$

= 
$$(15,450 \text{ 1b.}) \times (\$0.02525/1\text{b.}) + (565 \text{ 1b.}) \times (\$0.85/1\text{b.})$$

- = \$390.11 + \$480.25
- = \$870.36

Therefore, the expected gross income from daughters of Bull C is, on the average, \$870.36 under this pricing system.

## Appendix II

The formula for computing expected income for the daughters of a specific bull relative to the daughters of a breed average bull is:

# Equation 2

$$V = TA_m \times (P - D \times T_b) + TA_f \times (D \times 100\%)$$

where:

V is the expected total value for milk produced expressed as a deviation from the average income for the breed, and

TA<sub>m</sub>, P, D, T<sub>b</sub>, TA<sub>f</sub> are the same as defined in Appendix I.

# Example 4:

Set up to compute deviation income from breed average for bull's daughters according to the pricing system used in

table 15. The milk price is \$5.50/cwt. for 3.5% test, or P = \$0.055/1b. The test differential is \$0.085/0.1%/cwt, or D = \$0.0085/%/1b. (i.e., milk with 0.0% test is worth \$2.525/cwt.)

From equation 2:

$$V = TA_{m} \times (P - D \times T_{b}) + TA_{f} \times (D \times 100\%)$$

$$V = (TA_{m} \text{ in 1b.}) \times [\$0.055/1b. - (\$0.0085/\%/1b.) \times (3.5\%)]$$

$$+ (TA_{f} \text{ in 1b.}) \times (\$0.0085/\%/1b.) \times (100\%)$$

$$V = (TA_{m} \text{ in 1b.}) \times (\$0.02525/1b.) + (TA_{f} \text{ in 1b.})$$

$$\times (\$0.85/1b.)$$

This reduced equation simply indicates that the transmitting ability for milk will be multiplied by the value of a unit of 0.0 percent milk, and the transmitting ability for fat will be multiplied by the value of a unit of fat.

Index Bull C:

Bull C has a PD milk = +1,200 lb. and  
a PD fat = +40 lb.  

$$V = (1,200 lb.) \times (\$0.02525/lb.) + (40 lb.) \times (\$0.85/lb.)$$

$$= \$30.30 + \$34.00$$

$$= \$64.30$$

Therefore, under this pricing system, daughters of Bull C would be expected to average \$64.30 more gross income per lactation than their breed average herdmates.

TABLE 2. THE ADDITIONAL VALUE OF MILK EXPECTED OF THE DAUGHTERS OF BULLS OR COWS ACCORDING TO PREDICTED DIFFERENCES OR COW INDEXES FOR MILK AND FAT (BASED ON A PRICE OF \$4.50 PER HUNDRED POUNCS OF MILK HAVING 3.5% FAT AND A DIFFERENTIAL OF \$0.070 PER 0.1% PER CWT.)
